

List Overlap Comprehensions ♪ ♪

Exercise 10 (and [Solution](#))

This week's exercise is going to be revisiting an old exercise (see [Exercise 5](#)), except require the solution in a different way.

Take two lists, say for example these two:

```
a = [1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89]
b = [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13]
```

and write a program that returns a list that contains only the elements that are common between the lists (without duplicates). Make sure your program works on two lists of different sizes. Write this ~~in one line of Python~~ using at least one list comprehension. (Hint: Remember [list comprehensions](#) from Exercise 7).

The original formulation of this exercise said to write the solution using one line of Python, but a few readers pointed out that this was impossible to do without using sets that I had not yet discussed on the blog, so you can either choose to use the original directive and read about the [set command in Python 3.3](#), or try to implement this on your own and use at least one list comprehension in the solution.

Extra:

- Randomly generate two lists to test this
