

Read From File 🐍

Exercise 22 (and [Solution](#))

Given a `.txt` file that has a list of a bunch of names, count how many of each name there are in the file, and print out the results to the screen. I have a `.txt` file for you, if you want to [use it](#)!

Extra:

- Instead of using the `.txt` file from above (or instead of, if you want the challenge), take [this .txt file](#), and count how many of each “category” of each image there are. This text file is actually a list of files corresponding to the [SUN database](#) scene recognition database, and lists the file directory hierarchy for the images. Once you take a look at the first line or two of the file, it will be clear which part represents the scene category. To do this, you’re going to have to remember a bit about string parsing in Python 3. I talked a little bit about it [in this post](#).
